

Macroevolution and Phylogenetics

Macroevolution is evolution above the species level, and includes the origins and fates of major novelties, changes in diversity of lineages through time, and the impact of geological and other physical factors on the evolutionary process. Paleontology plays a central role in macroevolution. The fossil record provides insights onto large-scale evolutionary patterns, and thus documents macroevolutionary phenomena, and provides a natural laboratory for the framing and testing of macroevolutionary hypotheses.

Schopf 1972

Species-level selection and macro-evolution – the entire species lineage is the unit that differentially survives and/or reproduces. Requires emergent properties such as...

David Jablonski and geographic range

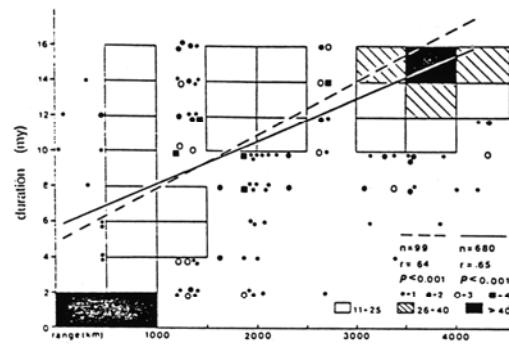

FIGURE 6. Scatterplot and regression of the results of our simulation using systematic sampling and a 1% resolution level (solid line). Dashed line is the regression obtained from plotting duration on range for a published set of prosobranch gastropod data from the Cretaceous of North America (Jablonski 1986: table 1). Duration = 0.0015 × Range + 2.44. N = 99, r = 0.64, P < 0.001. The two slopes are not significantly different ($P < 0.05$, t-test: Sokal and Rohlf 1981).

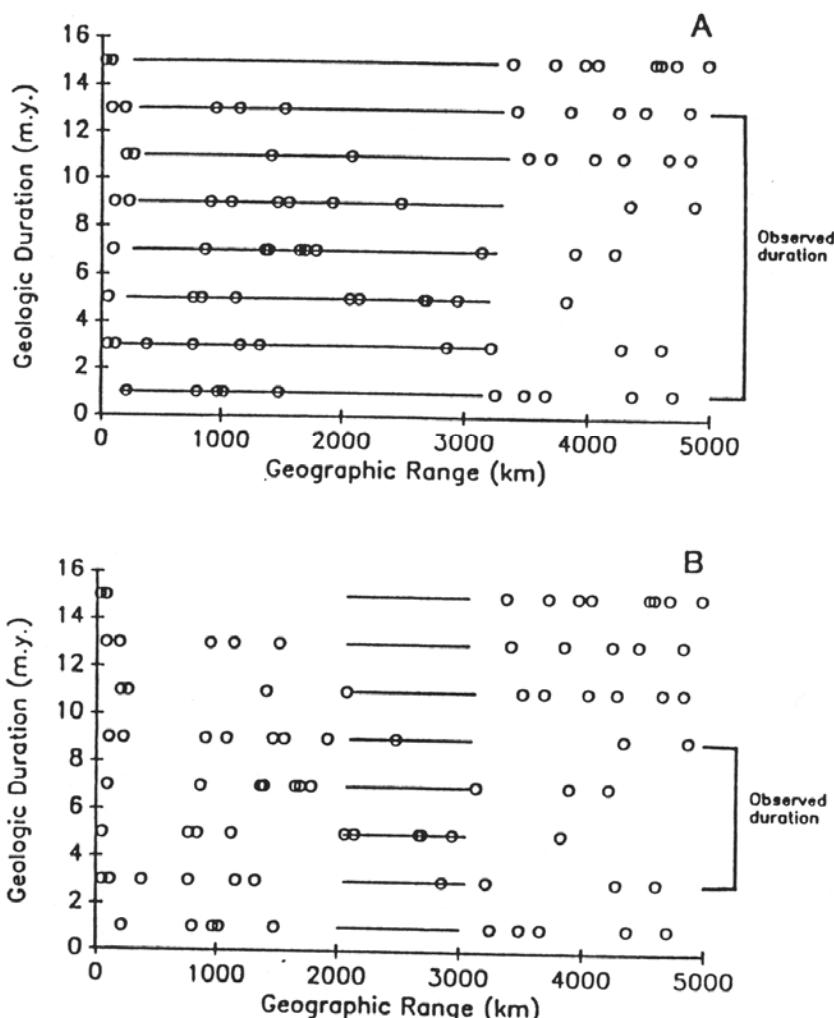

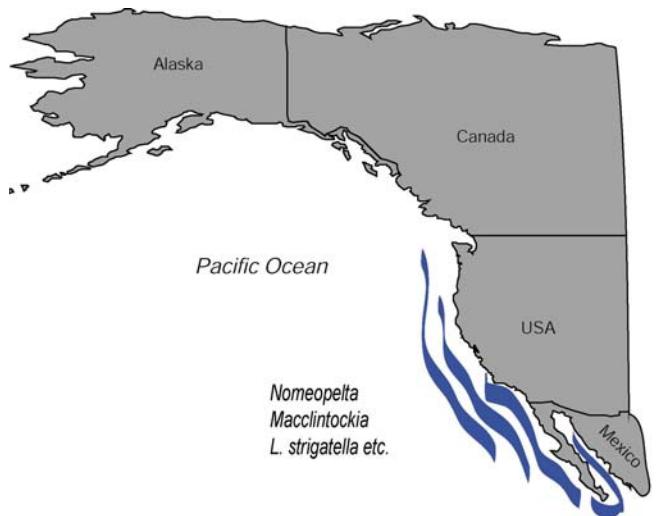

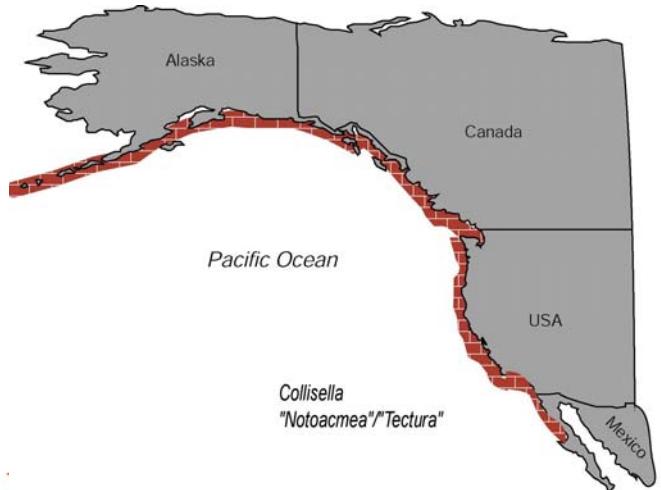

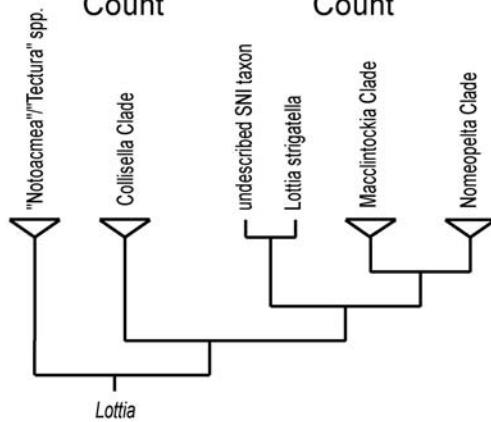

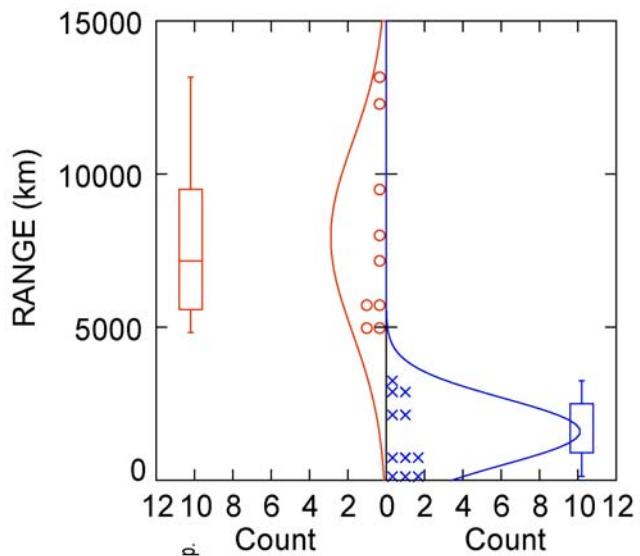

FIGURE 1. The geographic range of a species (X-axis) is represented as a horizontal line in the eight stratigraphic horizons (Y-axis). The circles represent fossil localities. Although there is no difference in the actual durations of the long-ranging (A) and short-ranging species (B), there is a difference in the observed durations. For the geographic range and geologic duration simulations, each plot represents a point along the species or Z-axis of the matrix.

Ranges

Size

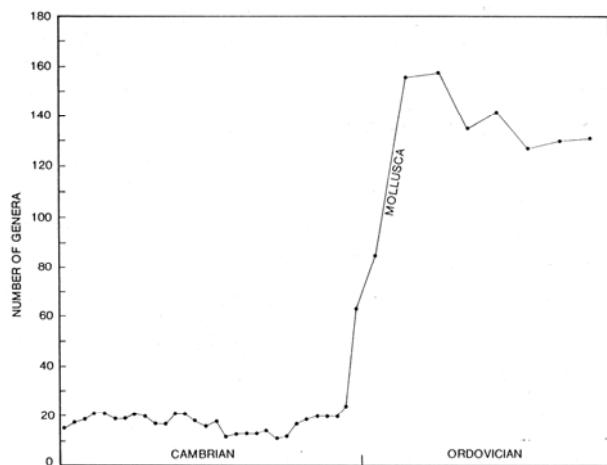

Fig. 2. Diversity of Cambrian and Ordovician molluscs (except cephalopods). All measurements shown are likely to be underestimates but the relative differences are probably correct. Modified from Runnegar (1982a), copyright Geological Society of Australia Incorporated, republished with permission.

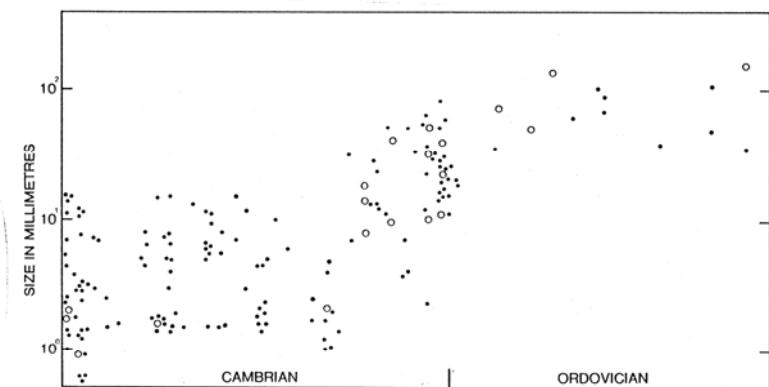

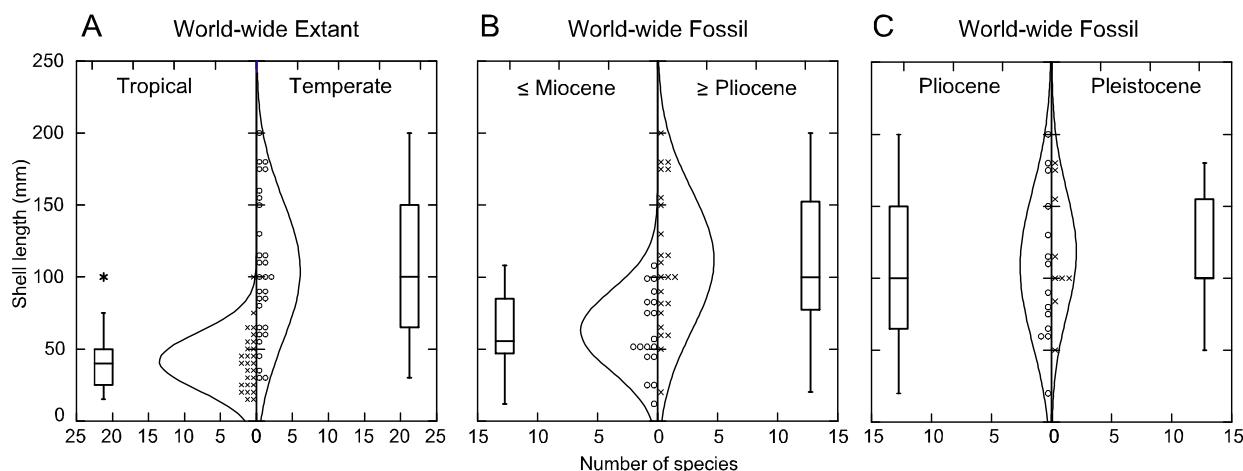

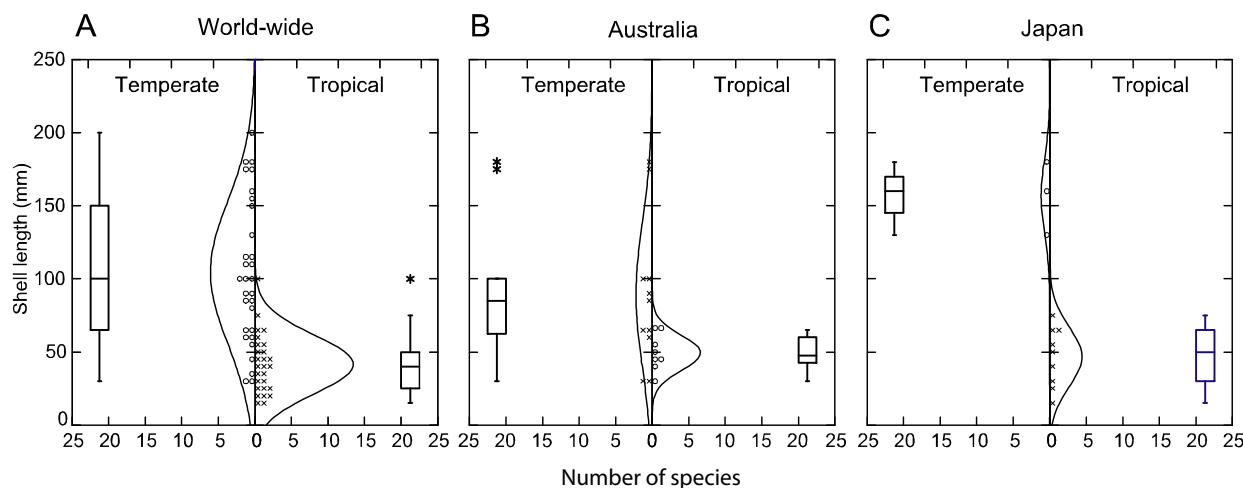

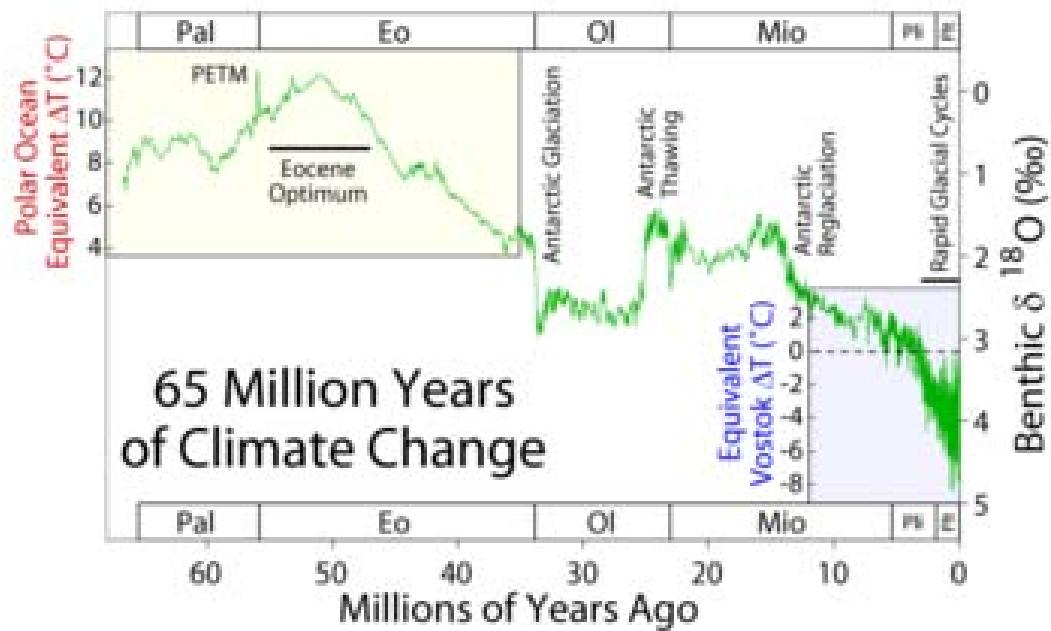

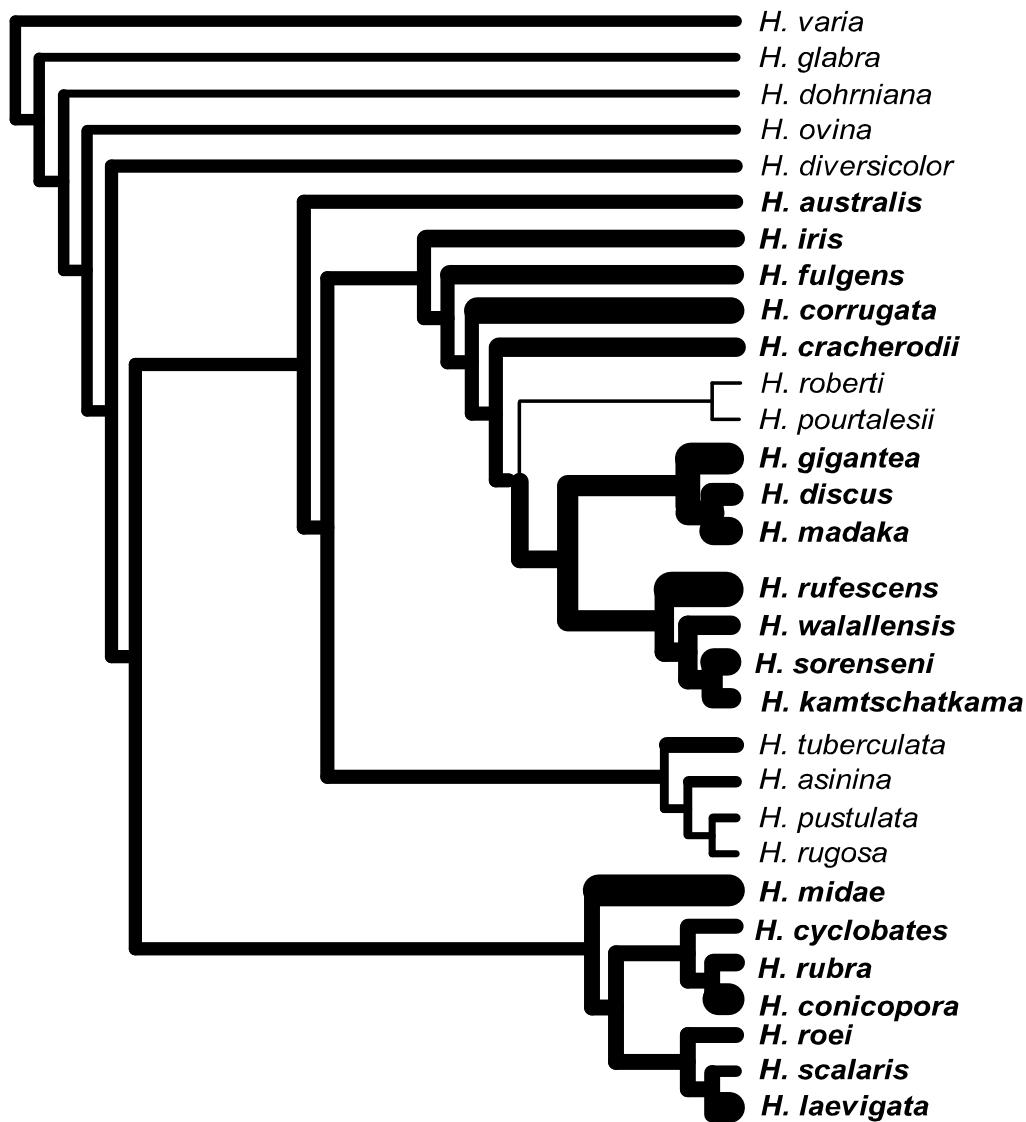

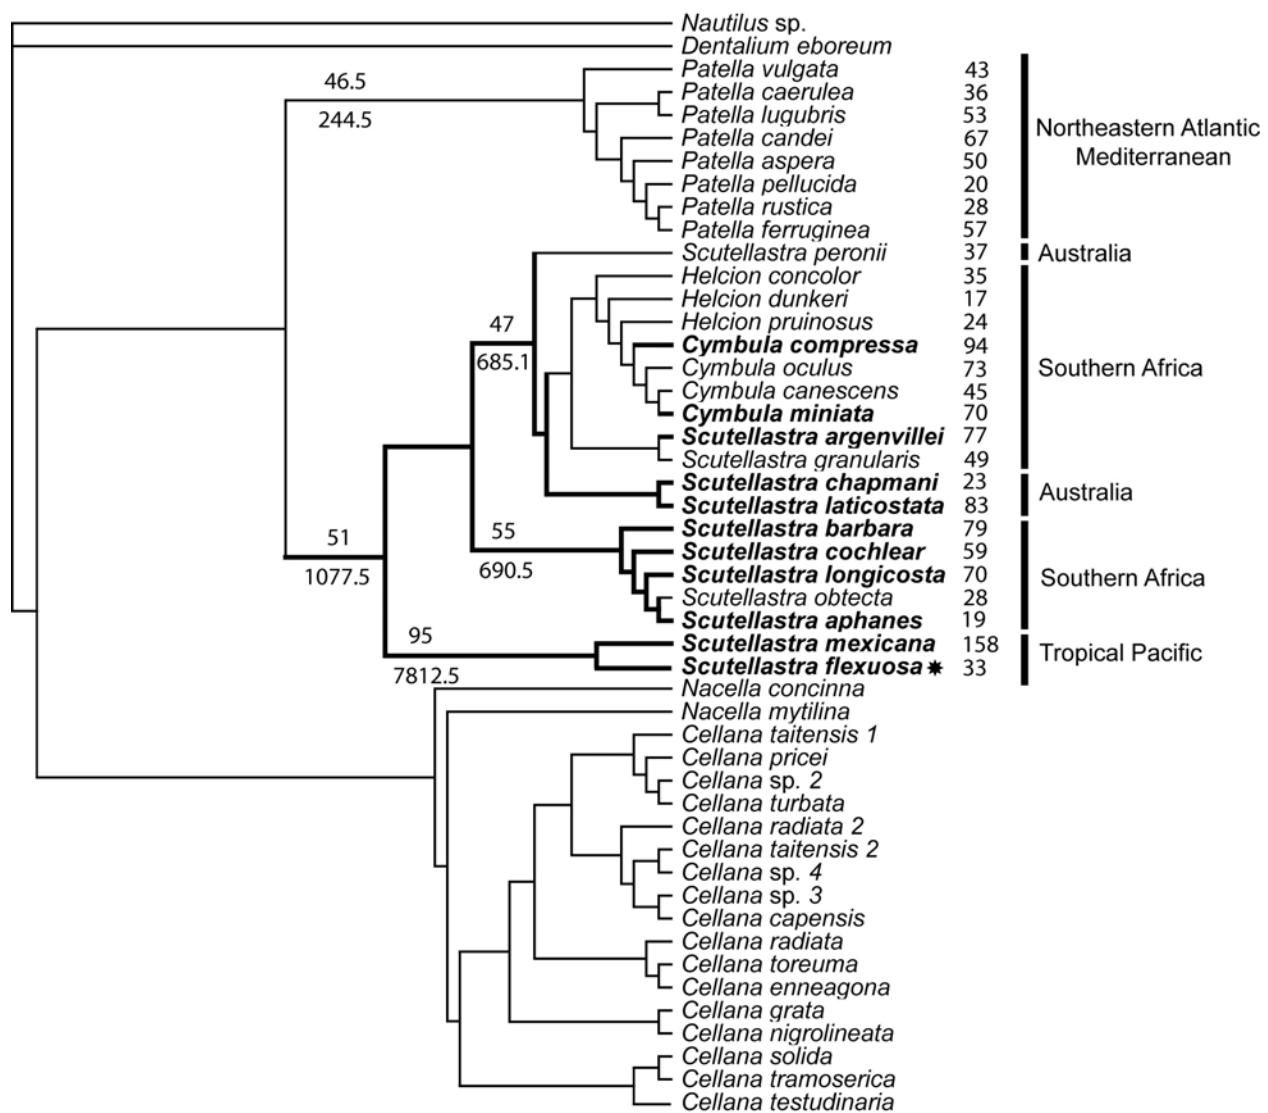

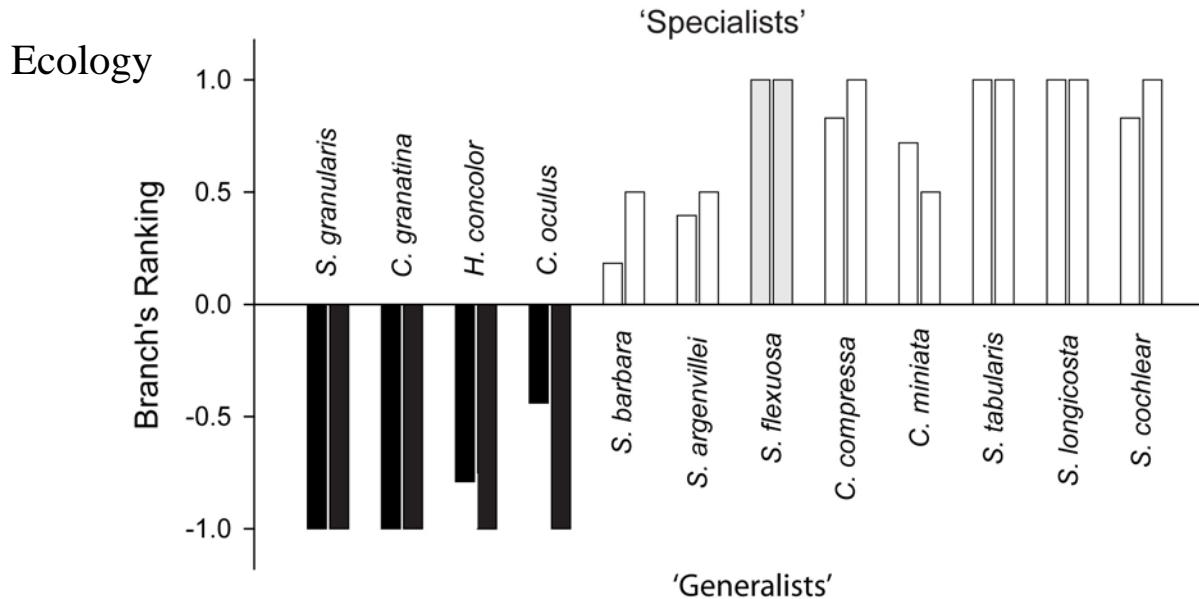

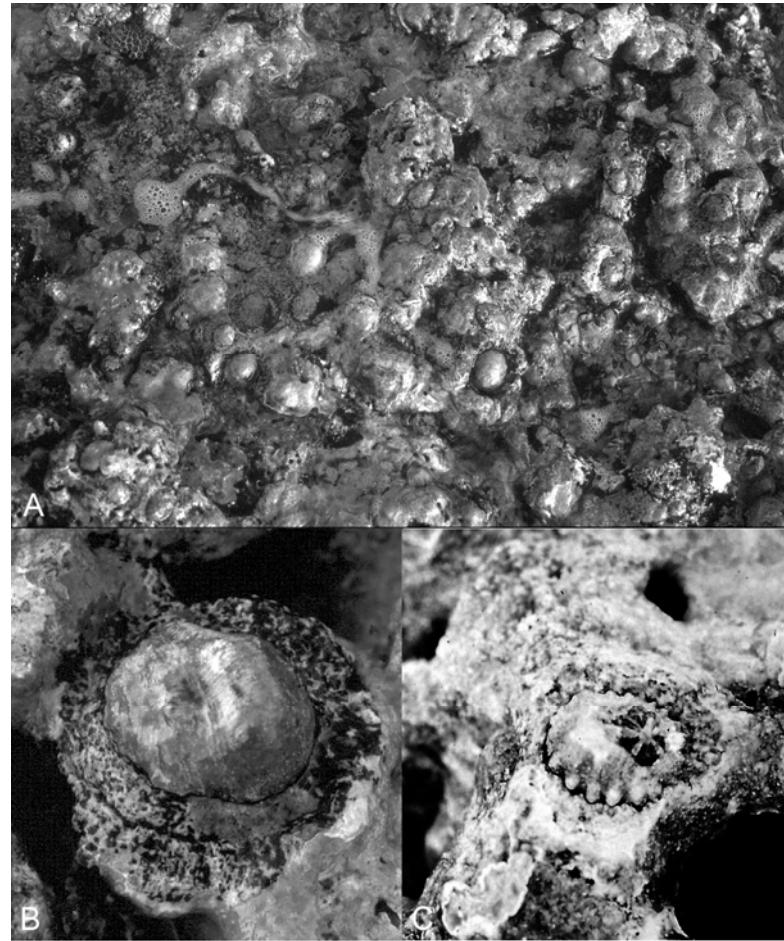

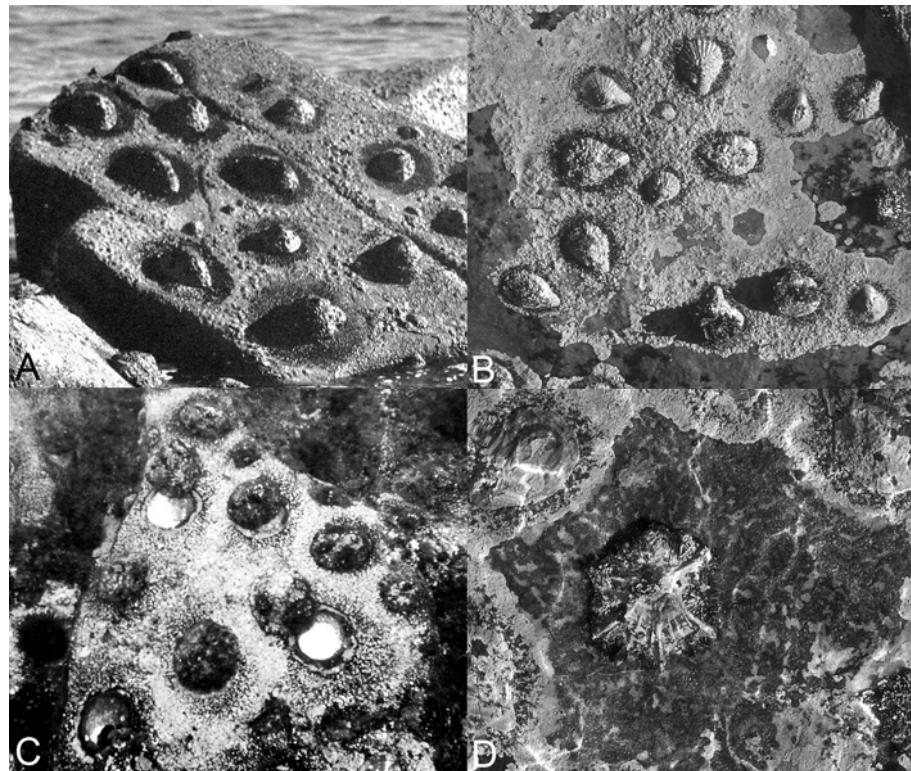

Fig. 3. Maximum size (longest dimension) of the largest measured individual of 173 species of Cambrian and Ordovician molluscs. Only a few large Ordovician molluscs were measured and plotted; the Cambrian points were selected from 375 measurements of published photographs and suitable available specimens.

Most kinds of molluscs became larger in the Late Cambrian and Ordovician. The open circles represent measurements made from a single lineage, the macluritacean snails *Nomgolitella* Missarzhevsky, *Cambrospira* Yu, *Bartskaia* Golubev, *Yuwenia* Runnegar, *Platyterias chironis* Walcott, *Protoscaeovigra* Kobayashi, *Kobayashihella* Endo, *Scaeovigra* Whitfield, *Matherella* Walcott, *Matherellina* Kobayashi, *Palliseria* Wilson, *Teichispira* Yochelson & Jones, *Maclurites* Lesueur (left to right). See Runnegar (1982a, fig. 4) for post-Ordovician data.

Mass Extinction Intervals

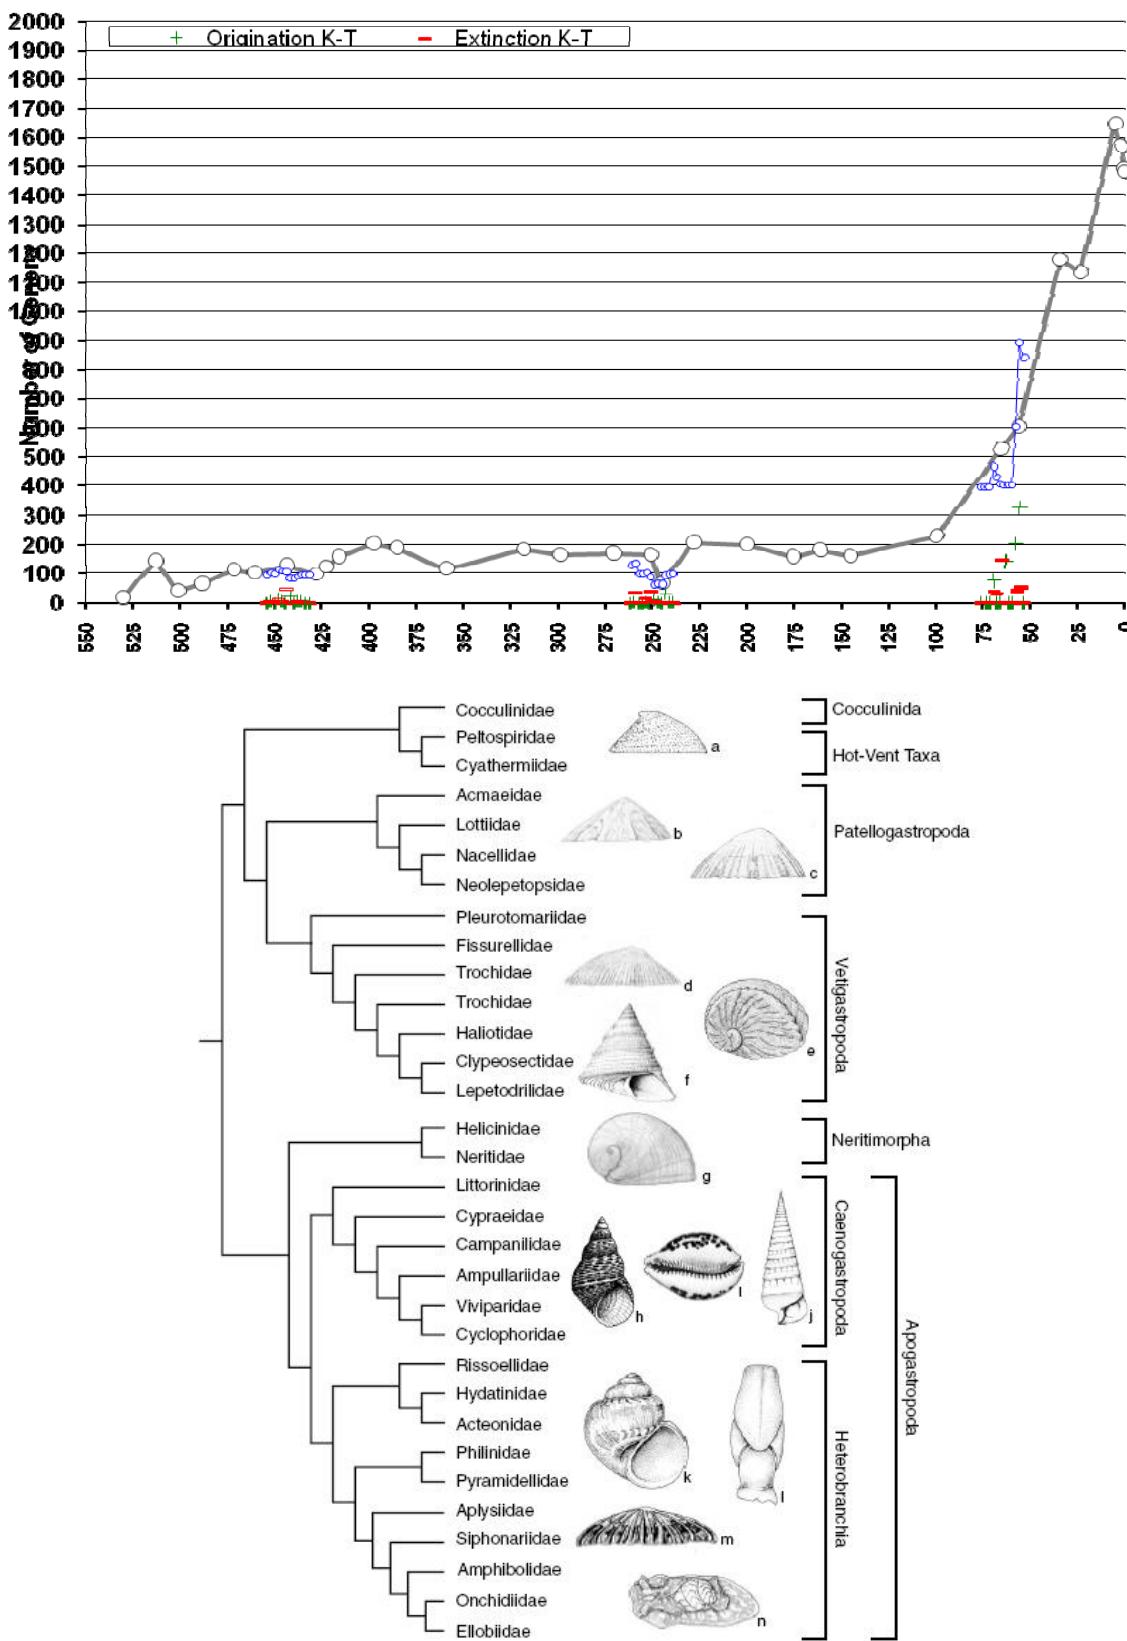

FIGURE 9.7. Schematic representation of gastropod relationships based on the optimal parameter set (12i) for the combined analysis of morphological and molecular data. See text for further details. Taxa represented in the figure are: (a) *Coccoxya hispida* (Cocculinidae); (b) *Patella da saccharina* (Lottiidae); (c) *Cellana tramoserica* (Nacellidae); (d) *Diodora lineata* (Fissurellidae); (e) *Halotis rubra* (Halitidae); (f) *Calicostoma* sp. (Trochidae); (g) *Nerita atramentosa* (Neritidae); (h) *Littoraria luteola* (Littorinidae); (i) *Cypraea tigris* (Cypraeidae); (j) *Campanile symbolicum* (Campanilidae); (k) *Phallomedusa solida* (Amphibolidae); (l) *Philine columnaria* (Philinidae); (m) *Siphonaria atra* (Siphonariidae); (n) *Micromelo undatus* (Hydatinidae).
